APPIOT : Lab 1 CoAP

<u>1/ Discovering Server Resources :</u>

In clientGet.py I changed the Uri by this 'coap://10.0.2.16/.well-known/core' and I obtained all the available resources in the server:

client:

```
GET.py
Result: 2.05 Content
b'</.well-known/core>;ct="40",</>,</time>;obs,</other/block>,</other/separate>;t
itle="A large resource",</whoami>,<https://christian.amsuess.com/tools/aiocoap/#
version-0.4.7.post0>;rel="impl-info"'
```

server:

DEBUG:coap-server:Incoming message <aiocoap.Message at 0x7f68d36cbca0: CON GET (MID 25039, token ad40) remote <UDP6EndpointAddress 10.0.2.15:37583 (locally 10.0 .2.16%enp0s3)>, 1 option(s)> DEBUG:coap-server:New unique message received DEBUG:coap-server:Sending message <aiocoap.Message at 0x7f68d2e8aa60: ACK 2.05 C ontent (MID 25039, token ad40) remote <UDP6EndpointAddress 10.0.2.15:37583 (loca lly 10.0.2.16%enp0s3)>, 1 option(s), 194 byte(s) payload>

2/ Analysing Traffic with Wireshark.

After capturing the traffic I obtained this:

			Le	oopback: lo						- 0	8
<u>F</u> ile	<u>E</u> dit <u>V</u> iew <u>G</u> o	<u>Capture</u> <u>A</u> nalyze	<u>Statistics</u> Telephony <u>W</u> ir	eless <u>T</u> ools	<u>H</u> elp						
	i 🙆 🚺	3 X []	। ९ 🔶 🔿 🖉 有	₹		Q Q 🏢	[
CC	ар									× →	• +
No.	Time	Source	Destination	Protocol	Length Info						
 *	5 2.822945978	10.0.2.15	10.0.2.16	COAP	65 CON,	MID:56868,	GET,	TKN:3d e	0, /.well-	known/cor	e
eL.	6 2.823957906	10.0.2.16	10.0.2.15	CoAP	245 ACK,	MID:56868,	2.05	Content,	TKN:3d e0	, /.well-	known/
											2

In the info section we can see CON, so the messages are confirmable.

For the other resources we have this:

/time:

No.	Time	Source	Destination	Protocol	Length Info						
	5 2.643488685	10.0.2.15	10.0.2.16	CoAP	53 CON,	MID:39268,	GET,	TKN:c3 f	d, /time	Î	
	6 2.644383707	10.0.2.16	10.0.2.15	CoAP	65 ACK,	MID:39268,	2.05	Content,	TKN:c3	fd,	/time

For this request, we have a new token designated as 'c3.' Additionally, the message ID and the length of the response have changed. The token remains consistent for each identical request, but it alters when the request changes. The message ID is updated with each new request, and the response length varies depending on the request specifics.

Here is another example with the request <u>other/separate</u>:

			Capculin	ig from Loopback: lo			🧕
<u>F</u> ile	<u>E</u> dit <u>V</u> iew <u>G</u> o	<u>Capture</u> <u>A</u> nalyze	Statistics Telephony W	ireless <u>T</u> ools <u>H</u> elp			
1	i 🧟 🔘 🛛		۹ 🔶 🛸 🐔 🐐	: ₹ 🗐 🗐 €	00	E	
					· ~ ~ ±		
Со	ар						*
No.	ap Time	Source	Destination	Protocol Length Ir	fo		* +
		Source 10.0.2.15	Destination	Protocol Lengtr Ir CoAP 63 C		, GET, TKN:ef b	► ★ +
	Time		TAKE TO STOLEN AND A CONTRACT OF	CoAP 63 C			be, /other/separate
	Time 5 0.545486461	10.0.2.15	10.0.2.16	CoAP 63 C CoAP 46 A	ON, MID:63710, CK, MID:63710,	, Empty Message	be, /other/separate

For this case we have this steps:

Packet #5: This is a confirmable CoAP GET request sent by the client. It requires an acknowledgment from the server to confirm that the request has been received.

Packet #6: The server sends an acknowledgment (ACK) back to the client. However, this ACK is an empty message, which means it's acknowledging receipt of the request without carrying the actual response data yet.

Packet #7: Subsequently, the server sends the response with the requested content in a separate confirmable message. This pattern is used when the server needs more time to prepare the response or wishes to separate the acknowledgment of the request from the response.

Packet #8: Finally, the client acknowledges the receipt of the response content with another ACK.

for <u>other/block:</u>

No.	Time	Source	Destination	Protocol	Length Info						
T*	21 32.665954276	10.0.2.15	10.0.2.16	CoAP	60 CON,	MID:50108,	GET,	TKN:72 5	5, /other	/block	8
1.	22 32.666840867	10.0.2.16	10.0.2.15	CoAP	1078 ACK,	MID:50108,	2.05	Content,	TKN:72 5	5, /ot	her/block

the token changed, the same for the length, the mid and the uri.

For the other resources it is the same the token, mid, uri and the number of packets changed.

<u>3/ GET Requests with and without Confirmation.</u>

Result of the command aiocoap-client coap://10.0.2.16/time :

The message is confirmable. The client send a request and the server send back the data with the ack.

aiocoap-client --non coap://10.0.2.16/time

5 6.278935779 10.0.2.15 10.0.2.16 CoAP 53 NON, MID:54178, GET, TKN:90 3b, /time 6 6.279795103 10.0.2.16 10.0.2.15 CoAP 65 NON, MID:20522, 2.05 Content, TKN:90	
6 6.279795103 10.0.2.16 10.0.2.15 COAP 65 NON, MID:20522, 2.05 Content, TKN:90	ime
	90 3b, /tim

The main difference between the two captures is the message type. The first capture shows a confirmable (CON) request that requires an acknowledgment (ACK) from the server, evidenced by the two-packet exchange. The second capture illustrates a non-confirmable (NON) request which doesn't require an ACK, resulting in just two messages: the request and the response.

4/ Message format analysis.

For the request **/time** we have:

Frame: Details about the data captured by Wireshark, including the length and bytes on the wire.

Ethernet II: Shows the source and destination MAC addresses, indicating the hardware-level communication.

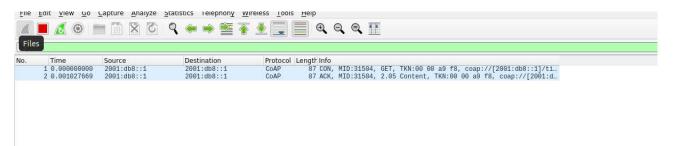

Internet Protocol Version 4 (IPv4): Includes source and destination IP addresses, differentiating services field, identification, flags, fragment offset, time to live (TTL), and protocol (indicating CoAP).

User Datagram Protocol (UDP): Displays the source and destination ports, important for identifying the CoAP messages.

Constrained Application Protocol (CoAP): Displays the protocol-specific information such as the message type (Acknowledgment), the message ID (MID), the request method (GET), the response code (2.05 Content), and the Token (TKN), which is used to match responses with requests.

5/ IPv6 configuration.

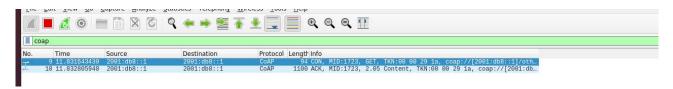

With the request "aiocoap-client coap://[2001:db8::1]/time" we have:

The source and destination addresses changed according to the IPv6 and the length is bigger than the request with IPv4.

6/ Large block transfer.

For the request **other/block**/ with payload equals to 1024 I have this:

For the request **other/block**/ with payload equals to 2048 I have this:

C	рар							
lo.	Time	Source	Destination	Protocol	Length Info			
-	5 1.751928762	2001:db8::1	2001;db8::1	CoAP	94 CON,	MID:16222,	GET,	TKN:00 00 93 e5, coap://[2001:db8::1]/ot

	11 7.612701030	2001:db8::1	2001:db8::1	CoAP	96 CON,	MID:22030.	GET.	TKN:00 00 b4 11, End of Block #3, coap:/.
	12 7.613637806	2001:db8::1	2001:db8::1	CoAP	1098 ACK,	MID:22030,	2.05	Content, TKN:00 00 b4 11, Block #3, coap.
	13 7.614944284	2001:db8::1	2001:db8::1	CoAP				TKN:00 00 b4 12, End of Block #4, coap:/.
	14 7.615881049	2001;db8;:1	2001:db8::1	COAP	76 ACK.	MID:22031.	2.05	Content, TKN:00 00 b4 12, End of Block #.

With increasing payload sizes, CoAP uses blockwise transfer to efficiently manage data transmission. For the 1024-byte payload, we see a simple two-message exchange, showing that it fits within a single CoAP message without the need for segmentation. However, with the 2048 and 4096-byte payloads, multiple CoAP messages are involved, indicating that the payload is divided into blocks. This is evident from the "Block" option in the CoAP header, which signifies that the message is part of a sequence of block transfers. The transfer of larger payloads results in more CoAP messages, as the payload must be split into sizes that conform to the network's MTU limits.

7/ PUT Request and Blockwise Handling.

We the script clientPUT.py (payload=1024) I have got this:

					Ca	pturing from Loopback: lo

The Wireshark captures showed that as the payload size increases, CoAP automatically employs blockwise transfer to handle the data. This is necessary because CoAP messages must stay within the size limits of the underlying transport, which for UDP is typically 1280 bytes for the path MTU (Maximum transmission unit). The larger payloads were segmented into blocks, each transferred in separate CoAP messages, as observed in the increasing number of packets captured for the larger sizes. This mechanism ensures reliable and efficient data transmission for constrained environments where large messages could lead to network congestion or loss.

8/ CoAP Observer Functionality.

In putting my ip address and I put the uri /time in the script client-observer.py, then I obtained this:

The script initially set up an observation relationship with a CoAP server resource. As expected, it received and printed the first notification of the current state of the resource. Subsequently, it printed updates whenever the observed resource changed.

I modified it to cease observation after receiving ten values. To achieve this, I added a counter variable that increments with each received notification. When the counter reached ten, the script executed the observation.cancel() method to stop receiving updates.

I replaced this line of code:

async for r in pr.observation :

i

i

1

1

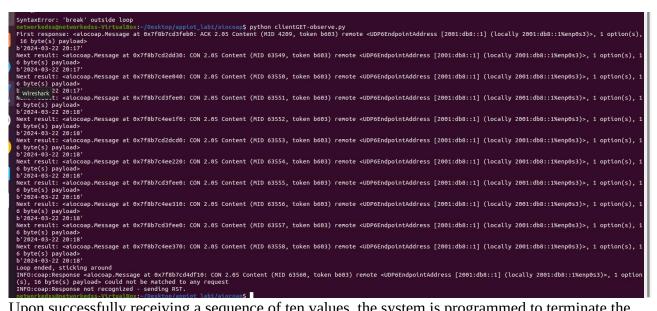

print(« Next result :%s\n%r » % (r,r.payload))

by this :

```
r = await pr.response
print("First response: %s\n%r"%(r, r.payload))
c=0
async for r in pr.observation:
    print("Next result: %s\n%r"%(r, r.payload))
    c+=1
    if c==10:
        pr.observation.cancel()
        break
print("Loop ended, sticking around")
await asyncio.sleep(50)
```

I implemented a counter called c and I stopped after 10 iterations.

Finally I obtain the good result which is :

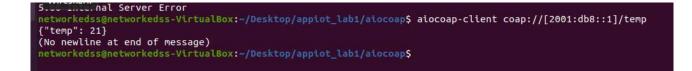

Upon successfully receiving a sequence of ten values, the system is programmed to terminate the observation, thereby stopping any further updates.

Second Part:

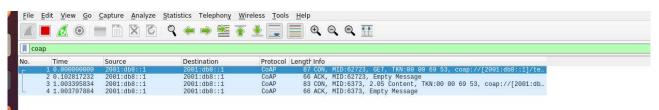

For doing the second part I modified the code server.py. I used the class TimeRessource for doing the new class call TempResource :

```
01
 88 class TempResource(resource.Resource):
 89
           def init (self):
 90
 91
                   super().__init__()
 92
                   self.handle = None
 93
 94
 95
           def notify(self):
 96
                   self.updated state()
 97
                   self.reschedule()
98
99
           def reschedule(self):
100
                   self.handle = asyncio.get event loop().call later(5, self.notify)
101
           def update observation count(self, count):
102
103
                   if count and self.handle is None:
104
                           print("Starting the clock")
                           self.reschedule()
105
106
                   if count == 0 and self.handle:
107
                           print("Stopping the clock")
                           self.handle.cancel()
108
109
                           self.handle = None
110
111
112
           async def render_get(self, request):
113
                   await asyncio.sleep 5
                   temp_value= random.randint(20,30)
114
                   payload = json.dumps({"temp": temp_value}).encode('utf-8')
115
                   return aiocoap.Message(payload=payload)
116
```

Just the function render_get changed. In the render_get function, a simulated delay of five seconds is introduced using asyncio.sleep(5) to emulate a time-consuming read operation, such as accessing a sensor or a database. A random temperature value between 20 and 30 is generated using random.randint(20, 30). This value is then formatted into a JSON string with json.dumps({"temp": temp_value}). Finally, this JSON string is encoded in 'utf-8' and sent back as the payload of the CoAP message with the content format set to application/json, making the response machine-readable and compliant with common data interchange standards. Finally I obtained this :

When using wireshark I obtained this :

we see a CoAP GET request and response sequence. The exchange begins with a CON message indicating a GET request from the client. The server promptly acknowledges this request with an empty ACK message, indicating that it has received the request but the content is not yet ready. After a deliberate delay - often used to emulate data processing or retrieval from a sensor - the server responds with the content in a CON message. Finally, the client sends an ACK to confirm the receipt of the content, completing the transaction.
